This guide provides a comprehensive overview of glycolysis and cellular respiration, offering answers to common study questions and highlighting key concepts for a thorough understanding. We'll delve into the processes step-by-step, providing helpful mnemonics, illustrative examples, and strategies to avoid common pitfalls. This guide is optimized for search engines using relevant keywords like "glycolysis," "cellular respiration," "Krebs cycle," "electron transport chain," "ATP production," and "study guide answers."

I. Understanding Glycolysis: The Sugar Breakdown

Glycolysis, meaning "sugar splitting," is the first stage of cellular respiration and occurs in the cytoplasm of the cell. It's an anaerobic process, meaning it doesn't require oxygen. The goal of glycolysis is

to break down glucose (a 6-carbon sugar) into two molecules of pyruvate (a 3-carbon molecule). This process generates a small amount of ATP (adenosine triphosphate), the cell's energy currency, and NADH, an electron carrier. Step-by-Step Glycolysis: 1.

Phosphorylation: Glucose is phosphorylated twice, using two ATP molecules. This makes it more reactive. 2. **Cleavage**: The 6-carbon molecule is split into two 3-carbon molecules (glyceraldehyde-3-phosphate). 3. Oxidation and Phosphorylation: Each 3-carbon molecule is oxidized, generating NADH and ATP (substrate-level phosphorylation). 4. Pyruvate Formation: The 3-carbon molecules are converted into pyruvate. **Net Gain in Glycolysis**: 2 ATP (4 produced - 2 consumed), 2 NADH, and 2 pyruvate molecules. **Mnemonic**: Remember the phases: **P**hosphorylation, **C**leavage, **O**xidation & **P**hosphorylation, **P**yruvate. (PCOPP)

II. Cellular Respiration: Harvesting Energy from Glucose

Cellular respiration is the process that extracts energy from glucose completely. It encompasses glycolysis (described above) and three subsequent stages that require oxygen: • Pyruvate Oxidation: Pyruvate moves into the mitochondria and is converted into Acetyl-CoA. This releases CO₂ and generates NADH. • **Krebs Cycle (Citric Acid Cycle)**: Acetyl-CoA enters the Krebs cycle, a series of reactions that release more CO₂ and generate ATP, NADH, and FADH₂ (another electron carrier). This cycle occurs within the mitochondrial matrix. • **Electron Transport Chain (ETC) and Oxidative Phosphorylation**: NADH and FADH₂ donate their electrons to the ETC, a series of protein complexes embedded in the inner mitochondrial membrane. As electrons move down the chain, protons

(H⁺) are pumped across the membrane, creating a proton gradient. This gradient drives ATP synthesis through chemiosmosis (oxidative phosphorylation). Oxygen acts as the final electron acceptor, forming water. **Net Gain in Cellular Respiration (per glucose molecule):** Approximately 30-32 ATP (the exact number varies slightly depending on the efficiency of the shuttle systems transporting NADH from the cytoplasm into the mitochondria).

III. Comparing Glycolysis and Cellular Respiration: A Side-by-Side Comparison

principles and the logic of each step. **Best Practices:** • **Use diagrams and visuals:** Drawing the pathways helps you visualize the process. • **Create flashcards:** Flashcards are excellent for memorizing key concepts and reactions. • **Practice questions:** Test your knowledge with practice problems and quizzes. • **Work through examples:** Use specific examples to understand the calculations and equations. • **Form study groups:** Discussing concepts with others enhances your understanding.

V. Examples and Applications

Example 1: During strenuous exercise, when oxygen supply is limited, muscles may switch to anaerobic respiration, relying primarily on glycolysis. This results in the production of lactic acid. **Example 2:** Yeast cells, in the absence of oxygen, perform alcoholic fermentation following glycolysis, producing ethanol and CO₂. **Example 3:** Mitochondrial diseases can disrupt cellular respiration, leading to reduced ATP production and various health problems.

VI. Summary

VII. FAQs

1. What is the role of oxygen in cellular respiration? Oxygen serves as the final electron acceptor in the electron transport chain. Without oxygen, the ETC would halt, and ATP production would drastically decrease. The process would revert to anaerobic respiration (fermentation). *2. How much ATP is produced during oxidative phosphorylation?* The majority of ATP (approximately 28-30 ATP) is produced during oxidative phosphorylation in the electron transport chain through chemiosmosis. **3. What are the differences between substrate-level phosphorylation and oxidative phosphorylation?** Substrate-level phosphorylation directly produces ATP by transferring a phosphate group from a substrate molecule (like in glycolysis and the Krebs cycle). Oxidative phosphorylation utilizes the proton gradient generated by the ETC to produce ATP through chemiosmosis. *4. What is fermentation, and why does it occur?* Fermentation is an anaerobic process that regenerates NAD⁺ from NADH, allowing glycolysis to continue in the absence of oxygen. This happens because oxygen isn't available to accept electrons in the ETC. **5. How can I best remember the Krebs cycle intermediates?** Use mnemonics or create a visual diagram to memorize the order of intermediates in the Krebs cycle. Relate the structure of each molecule to its function within the cycle. Start at Citrate, and systematically track the changes step-by-step, noting which molecules gain or lose carbons or other functional groups.

Glycolysis and Respiration: Your

Ultimate Study Guide Answers

So, you're diving into the fascinating world of cellular energy production, specifically focusing on glycolysis and cellular respiration. It's a core concept in biology, and understanding it is key to unlocking many other biological processes. But let's be honest, the textbooks and lecture notes can sometimes feel like a dense forest. That's where a good study guide comes in handy, and we're here to break down the essential answers you need to ace your understanding of glycolysis and respiration. Think of glycolysis and respiration as the ultimate energy-generating machinery within your cells. They're responsible for converting the food you eat into usable energy that powers everything from your brain to your biceps. We'll explore each stage, its significance, and the key players involved.

What is Glycolysis? The Foundation of Energy Production

Let's start at the beginning: glycolysis. The name itself gives us a clue: "glyco" refers to sugar (specifically glucose), and "lysis" means to break. So, glycolysis is essentially the "sugar-splitting" process. This is the very first stage of cellular respiration and occurs in the cytoplasm of almost every cell in your body.

The Glycolysis Pathway: A Step-by-Step Breakdown

Glycolysis is a metabolic pathway that involves a series of ten enzyme-catalyzed reactions. It's a complex dance, but we can simplify it into two main phases: the energy-investment phase and the energy-payoff phase.

Phase 1: Energy Investment

Before your cells can get energy *out* of glucose, they have to put a little energy *in*. In this initial phase, two molecules of ATP (adenosine triphosphate) are consumed to destabilize the glucose molecule and prepare it for further breakdown. This might seem counterintuitive, but it's a crucial step to get the ball rolling. The glucose molecule is phosphorylated twice, forming fructose-1,6-bisphosphate.

Phase 2: Energy Payoff

Once glucose has been primed, the energy payoff phase begins. Here, the six-carbon fructose-1,6-bisphosphate is split into two three-carbon molecules. These molecules are then further processed through a series of reactions that generate ATP and a crucial electron carrier called NADH.

The Net Yield of Glycolysis

So, what's the takeaway from this entire process? For each molecule of glucose that enters glycolysis, there's a net gain of: **2 molecules of ATP:** Remember, we invested 2 ATP and produced 4 ATP, resulting in a net gain of 2. This ATP is the immediate energy currency of the cell. **2 molecules of NADH:** These are high-energy electron carriers. Think of them as tiny rechargeable batteries that will be vital for later stages of respiration. **2 molecules of pyruvate:** This three-carbon molecule is the end product of glycolysis. Pyruvate is a key intermediate that can enter different pathways depending on the availability of oxygen.

Anaerobic vs. Aerobic Respiration: The Fate of Pyruvate

This is a critical point. What happens to pyruvate after glycolysis depends on whether oxygen is present. * **Anaerobic conditions (no oxygen):** If oxygen is scarce, cells resort to **fermentation**. In humans and many other organisms, this typically involves converting pyruvate into lactate (lactic acid fermentation). This process regenerates NAD⁺ from NADH, allowing glycolysis to continue producing a small amount of ATP. Muscle cells undergoing intense exercise often rely on lactic acid fermentation. In yeast, fermentation produces ethanol and carbon dioxide, a process vital for baking and brewing. * **Aerobic conditions (oxygen present):** This is where the real energy party begins! If oxygen is available, pyruvate enters the mitochondria for the subsequent stages of cellular respiration, which yield much more ATP.

Cellular Respiration: The Powerhouse Process

Cellular respiration is a more comprehensive process that follows glycolysis. It's the aerobic breakdown of glucose (and other fuel molecules) to produce a large amount of ATP. It involves a series of interconnected pathways, primarily occurring within the mitochondria.

The Mitochondria: The Cell's Powerhouse

You've likely heard of mitochondria as the "powerhouses" of the cell, and for good reason. These organelles are specialized for cellular respiration. They have a unique structure with an inner and outer membrane. The inner membrane is highly folded into structures called cristae, which significantly increase the surface area for ATP

synthesis.

The Stages of Aerobic Respiration (Following Glycolysis)

After glycolysis, if oxygen is present, pyruvate embarks on a journey through the mitochondria.

Stage 1: Pyruvate Oxidation (Link Reaction)

Before entering the main metabolic cycles, pyruvate undergoes a transformation. It's transported into the mitochondrial matrix and converted into a two-carbon molecule called acetyl-CoA. During this process: * One carbon atom is released as carbon dioxide (CO₂). * NAD⁺ is reduced to NADH. This step acts as a crucial link between glycolysis and the next major stage.

Stage 2: The Citric Acid Cycle (Krebs Cycle or TCA Cycle)

The acetyl-CoA then enters the **citric acid cycle**, a series of reactions that completely oxidizes the remaining carbon atoms. This cycle is named after citric acid, one of the first molecules formed. Key outcomes of the citric acid cycle: * **More CO₂ production:** The remaining carbon atoms from the original glucose molecule are released as carbon dioxide. * **ATP generation:** A small amount of ATP (or GTP, which is readily converted to ATP) is produced directly. * **Significant NADH and FADH₂ production:** This cycle generates a substantial number of high-energy electron carriers: NADH and FADH₂. These molecules are the stars of the next stage. For every turn of the cycle (which processes one acetyl-CoA molecule, derived from one pyruvate), you get: 3 NADH, 1 FADH₂, and 1 ATP (or GTP). Since glycolysis yields two pyruvates from one glucose, the citric acid cycle effectively runs twice per glucose molecule.

Stage 3: Oxidative Phosphorylation (Electron Transport Chain and Chemiosmosis)

This is where the magic truly happens in terms of ATP production.

Oxidative phosphorylation is a two-part process: * **Electron Transport Chain (ETC):** The NADH and FADH₂ molecules produced in the previous stages deliver their high-energy electrons to a series of protein complexes embedded in the inner mitochondrial membrane. As electrons are passed from one complex to another, they release energy. This energy is used to pump protons (H⁺) from the mitochondrial matrix into the intermembrane space, creating a proton gradient. * **Chemiosmosis:** The proton gradient represents stored potential energy. Protons flow back into the mitochondrial matrix through a special enzyme called **ATP synthase**. This flow of protons powers ATP synthase, which catalyzes the phosphorylation of ADP to ATP. This is the primary mechanism for ATP generation in cellular respiration. The final electron acceptor in the ETC is oxygen. Oxygen combines with electrons and protons to form water (H₂O). This is why oxygen is so essential for aerobic respiration.

The Grand Total: ATP Yield from Cellular Respiration

While the exact ATP yield can vary slightly depending on cellular conditions and how efficiently the intermediates are processed, a general estimate for the complete aerobic respiration of one glucose molecule is around **30-32 ATP molecules**. This is a massive increase compared to the meager 2 ATP from glycolysis alone!

Key Terms and Concepts to Remember

As you study glycolysis and respiration, keep these essential terms and concepts in mind: * **ATP (Adenosine Triphosphate):** The

primary energy currency of the cell. * **ADP (Adenosine Diphosphate):** The precursor to ATP. * **NAD⁺ and NADH:** Electron carrier molecules. NAD⁺ accepts electrons and a proton to become NADH. * **FAD and FADH₂):** Another pair of electron carrier molecules. FAD accepts two electrons and two protons to become FADH₂. * **Glucose:** The six-carbon sugar that is the primary fuel for glycolysis. * **Pyruvate:** The three-carbon molecule that is the end product of glycolysis. * **Mitochondria:** The organelles where aerobic respiration (after glycolysis) takes place. * **Mitochondrial Matrix:** The innermost compartment of the mitochondria. * **Inner Mitochondrial Membrane:** Where the electron transport chain and ATP synthase are located. * **Cristae:** Folds of the inner mitochondrial membrane that increase surface area. * **Acetyl-CoA:** A two-carbon molecule that enters the citric acid cycle. * **Carbon Dioxide (CO₂):** A waste product of cellular respiration. * **Water (H₂O):** Formed when oxygen accepts electrons and protons at the end of the ETC. * **ATP Synthase:** The enzyme that produces ATP during chemiosmosis. * **Fermentation:** An anaerobic process that regenerates NAD⁺ for glycolysis. * **Lactic Acid Fermentation:** Produces lactate. * **Alcoholic Fermentation:** Produces ethanol and CO₂. * **Oxidative Phosphorylation:** The process of ATP synthesis driven by the oxidation of electron carriers. * **Electron Transport Chain (ETC):** A series of protein complexes that transfer electrons and pump protons. * **Chemiosmosis:** The process of ATP synthesis driven by a proton gradient.

Common Pitfalls and How to Avoid Them

* **Confusing aerobic and anaerobic respiration:** Remember that glycolysis can occur with or without oxygen, but the subsequent stages of aerobic respiration *require* oxygen. * **Forgetting the role

of electron carriers:** NADH and FADH₂ are not just passive participants; they are crucial for transferring energy to the ETC. *

Underestimating the importance of the proton gradient: The proton gradient is the driving force behind ATP synthesis in oxidative phosphorylation. *

Memorizing without understanding: Try to visualize the flow of molecules and energy through each pathway. Understanding the "why" behind each step will make it much easier to remember.

Beyond Glucose: Other Fuel Sources

While glucose is the primary focus, it's important to remember that other molecules, like fatty acids and amino acids, can also be broken down and enter the cellular respiration pathways at different points to generate ATP. This highlights the interconnectedness of metabolism.

Understanding Glycolysis and Respiration: A Comprehensive Study Guide

Glycolysis and respiration form the cornerstone of cellular energy production, serving as fundamental biological processes that sustain life at the molecular level. At its core, glycolysis is the first major metabolic pathway, occurring in the cytoplasm of nearly all living cells, where one molecule of glucose—typically six carbon atoms—is broken down into two molecules of pyruvate, each containing three carbons. This anaerobic process, meaning it does not require oxygen, generates a net gain of two ATP molecules and two NADH, acting as the foundational step that fuels subsequent energy-harvesting reactions. The significance of glycolysis extends far beyond its simple output. It serves as a universal entry point for glucose metabolism, linking diverse metabolic pathways and enabling cells to rapidly produce energy even in oxygen-deprived environments. This makes glycolysis essential not only in aerobic organisms but also in anaerobic bacteria and even in specialized cells like those of the human muscle during intense exercise. Understanding glycolysis provides crucial insight into how cells adapt energy production to varying environmental conditions and metabolic demands.

From Glycolysis to Respiration: The Flow of Energy

Once pyruvate is formed, the journey continues into the mitochondria, where aerobic respiration takes over. This intricate sequence begins

with the conversion of pyruvate into acetyl-CoA, a process that bridges glycolysis to the Krebs cycle, or citric acid cycle. Here, acetyl-CoA undergoes a series of complex chemical transformations, releasing carbon dioxide and generating high-energy electron carriers—NADH and FADH₂—that carry electrons to the electron transport chain. As electrons flow through protein complexes embedded in the inner mitochondrial membrane, protons are pumped across the membrane, creating an electrochemical gradient. This gradient powers ATP synthase, a remarkable molecular machine responsible for producing the majority of ATP during oxidative phosphorylation, the final stage of respiration. This whole process exemplifies nature's efficiency in energy conversion, transforming the chemical energy stored in glucose into usable ATP with remarkable precision. The integration of glycolysis, the Krebs cycle, and oxidative phosphorylation illustrates a finely tuned system that maximizes energy yield while maintaining cellular homeostasis. For students studying respiration and metabolism, mastering this sequence is key to grasping how organisms extract energy from nutrients and sustain biological functions.

Unlocking the Secrets of Energy Production: A Deep Dive into Glycolysis and Respiration Study Guide Answers

The fundamental process of life hinges on the efficient conversion of energy. At the heart of this energy metabolism lie two interconnected pathways: glycolysis and cellular respiration. For students grappling with the intricacies of these biochemical marvels, a well-structured study guide, complete with insightful answers, is an invaluable asset. This article delves into the core concepts of glycolysis and cellular respiration, offering detailed explanations and answering common questions to foster a robust understanding.

The Gateway to Energy: Understanding Glycolysis

Glycolysis, derived from the Greek words "glykys" (sweet) and "lysis" (splitting), is the initial and universal pathway for glucose breakdown. It occurs in the cytoplasm of virtually all living cells, both prokaryotic and eukaryotic. This anaerobic process, meaning it doesn't require oxygen, serves as the first step in extracting energy from carbohydrates. The net result of glycolysis is the conversion of one molecule of glucose (a six-carbon sugar) into two molecules of pyruvate (a three-carbon molecule).

Key Stages and Reactions of Glycolysis

Glycolysis is a ten-step metabolic pathway, broadly divided into two phases: the energy-investment phase and the energy-payoff phase.

1. Energy-Investment Phase: Priming the Pump

This phase requires the input of ATP to destabilize the glucose molecule and prepare it for cleavage. Key steps include:

1. **Hexokinase/Glucokinase:** Glucose is phosphorylated to glucose-6-phosphate. This traps glucose within the cell and makes it more reactive.
2. **Phosphoglucose Isomerase:** Glucose-6-phosphate is isomerized to fructose-6-phosphate.
3. **Phosphofructokinase-1 (PFK-1):** Fructose-6-phosphate is phosphorylated to fructose-1,6-bisphosphate. This is a crucial regulatory step, often considered the rate-limiting enzyme of glycolysis.
4. **Aldolase:** Fructose-1,6-bisphosphate is cleaved into two three-

carbon molecules: glyceraldehyde-3-phosphate (G3P) and dihydroxyacetone phosphate (DHAP).

5. **Triose Phosphate Isomerase:** DHAP is isomerized to G3P, ensuring that both molecules entering the next phase are in the form of G3P.

2. Energy-Payoff Phase: Harvesting the Energy

In this phase, the two molecules of G3P are further processed, leading to the production of ATP and NADH. Key steps include:

1. **Glyceraldehyde-3-phosphate Dehydrogenase:** G3P is oxidized and phosphorylated to 1,3-bisphosphoglycerate. This reaction also reduces NAD^+ to NADH, capturing high-energy electrons.
2. **Phosphoglycerate Kinase:** 1,3-bisphosphoglycerate transfers a phosphate group to ADP, generating ATP. This is the first ATP production step.
3. **Phosphoglycerate Mutase:** 1,3-bisphosphoglycerate is rearranged to 3-phosphoglycerate.
4. **Enolase:** 3-phosphoglycerate is dehydrated to phosphoenolpyruvate (PEP), a high-energy phosphate compound.
5. **Pyruvate Kinase:** PEP transfers its phosphate group to ADP, generating another molecule of ATP. This is the second ATP production step.

Net Products of Glycolysis

For each molecule of glucose entering glycolysis, the net products are:

1. 2 molecules of Pyruvate
2. 2 molecules of ATP (4 produced, 2 consumed)
3. 2 molecules of NADH

The NADH produced during glycolysis carries high-energy electrons that can be further utilized in cellular respiration to generate significantly more ATP, provided oxygen is available. The pyruvate molecules are also critical intermediates, feeding into subsequent energy-generating pathways.

The Powerhouse of the Cell: Cellular Respiration Explained

Cellular respiration is the process by which cells break down glucose and other fuel molecules in the presence of oxygen to produce ATP, the primary energy currency of the cell. While glycolysis is the initial breakdown of glucose, cellular respiration encompasses the subsequent, more energy-efficient stages that occur in the mitochondria of eukaryotic cells.

The Link Reaction: From Pyruvate to Acetyl-CoA

Before entering the Krebs cycle, pyruvate must be converted into acetyl-CoA. This occurs in the mitochondrial matrix and involves a process called oxidative decarboxylation. One molecule of pyruvate is converted into one molecule of acetyl-CoA, releasing one molecule of CO₂ and producing one molecule of NADH. Since glycolysis produces two pyruvate molecules per glucose, this link reaction occurs twice per glucose molecule.

1. **Pyruvate Dehydrogenase Complex:** This multi-enzyme complex catalyzes the conversion of pyruvate to acetyl-CoA.

The Citric Acid Cycle (Krebs Cycle): The Central Hub of Energy

Production

The citric acid cycle, also known as the Krebs cycle or TCA cycle, is a series of chemical reactions that completes the oxidation of glucose. It occurs in the mitochondrial matrix and plays a central role in both catabolic and anabolic pathways. For each acetyl-CoA molecule that enters the cycle (meaning two turns per glucose molecule), the following products are generated:

1. 2 molecules of CO₂ (waste product)
2. 3 molecules of NADH
3. 1 molecule of FADH₂
4. 1 molecule of ATP (or GTP, which is readily converted to ATP)

The cycle begins with acetyl-CoA combining with oxaloacetate to form citrate. Through a series of enzymatic reactions, citrate is oxidized and rearranged, ultimately regenerating oxaloacetate, allowing the cycle to continue. The NADH and FADH₂ produced are crucial electron carriers that will fuel the next stage of respiration.

Oxidative Phosphorylation: The ATP Synthesis Masterpiece

Oxidative phosphorylation is the most significant ATP-producing stage of cellular respiration. It consists of two coupled processes: the electron transport chain (ETC) and chemiosmosis, both occurring on the inner mitochondrial membrane.

1. Electron Transport Chain (ETC):

The NADH and FADH₂ molecules generated from glycolysis, the link reaction, and the citric acid cycle deliver their high-energy electrons to a series of protein complexes embedded in the inner mitochondrial membrane. As electrons are passed from one complex to another, energy is released. This energy is used to pump protons (H⁺) from

the mitochondrial matrix into the intermembrane space, creating a proton gradient. Oxygen acts as the final electron acceptor, combining with electrons and protons to form water. Without oxygen, the ETC would halt, and ATP production would be severely limited.

2. Chemiosmosis: Harnessing the Proton Gradient

The proton gradient established by the ETC represents a form of potential energy. Protons flow back into the mitochondrial matrix down their electrochemical gradient through a special enzyme called ATP synthase. This flow of protons drives the synthesis of ATP from ADP and inorganic phosphate. This process is analogous to water flowing through a turbine to generate electricity.

Total ATP Yield from Cellular Respiration

The theoretical maximum ATP yield from one molecule of glucose through aerobic respiration is approximately 30-32 ATP molecules. However, the actual yield can vary due to factors such as the efficiency of the proton pumps and the energy cost of transporting molecules into the mitochondria. Nevertheless, this is significantly more ATP than can be produced through anaerobic pathways alone.

Anaerobic Respiration and Fermentation: When Oxygen is Scarce

In the absence of oxygen, cells cannot perform aerobic respiration. Glycolysis still occurs, producing pyruvate and a small amount of ATP. To regenerate NAD⁺ from NADH, allowing glycolysis to continue, cells resort to anaerobic respiration or fermentation.

Fermentation Pathways

Fermentation regenerates NAD^+ by transferring electrons from NADH to pyruvate or its derivatives. Two common types are:

1. **Lactic Acid Fermentation:** Occurs in muscle cells during strenuous exercise and in some bacteria. Pyruvate is reduced to lactate, regenerating NAD^+ . This process yields only the 2 ATP from glycolysis.
2. **Alcoholic Fermentation:** Occurs in yeast and some plant cells. Pyruvate is converted to acetaldehyde, which is then reduced to ethanol, regenerating NAD^+ . This process also yields only the 2 ATP from glycolysis.

While fermentation allows for ATP production in anaerobic conditions, it is far less efficient than aerobic respiration. The study of these pathways highlights the adaptability of cellular metabolism to different environmental conditions.

Questions & Answers About glycolysis and respiration study guide answers

No	Question	Answer
----	----------	--------

1	What is the primary goal of glycolysis, and where does it occur in the cell?	The primary goal of glycolysis is to break down glucose (a 6-carbon sugar) into two molecules of pyruvate (a 3-carbon molecule). This process extracts a small amount of energy in the form of ATP and NADH. Glycolysis occurs in the cytoplasm of the cell.
2	Can glycolysis happen without oxygen? Explain.	Yes, glycolysis is an anaerobic process, meaning it does not directly require oxygen. It can proceed in both the presence and absence of oxygen.
3	What are the net products of glycolysis per molecule of glucose?	Per molecule of glucose, the net products of glycolysis are 2 ATP molecules, 2 NADH molecules, and 2 pyruvate molecules.
4	What happens to pyruvate after glycolysis if oxygen is present?	If oxygen is present, pyruvate enters the mitochondria and is further processed through the Krebs cycle (also known as the citric acid cycle) and oxidative phosphorylation to generate a large amount of ATP.
5	What happens to pyruvate after glycolysis if oxygen is NOT present? (Mention fermentation)	If oxygen is absent, pyruvate undergoes fermentation. In humans, this typically results in the production of lactic acid. In yeast, it leads to the production of ethanol and carbon dioxide. Fermentation regenerates NAD ⁺ needed for glycolysis to continue.
6	Briefly describe the Krebs cycle and its main contribution to cellular respiration.	The Krebs cycle (citric acid cycle) is a series of chemical reactions that occur in the mitochondrial matrix. It further oxidizes the acetyl-CoA (derived from pyruvate) to produce ATP, NADH, and FADH ₂ . Its main contribution is generating electron carriers (NADH and FADH ₂) that will be used in the final stage of respiration.

7	What is the role of the electron transport chain (ETC) and oxidative phosphorylation in cellular respiration?	The electron transport chain, located in the inner mitochondrial membrane, uses the energy from electrons carried by NADH and FADH ₂ to pump protons across the membrane, creating a proton gradient. Oxidative phosphorylation uses this gradient to synthesize a large amount of ATP as protons flow back into the matrix through ATP synthase.
8	Why is oxygen considered the final electron acceptor in aerobic respiration?	Oxygen is the final electron acceptor because it has a high electronegativity, allowing it to readily accept electrons at the end of the electron transport chain. This process forms water and drives the proton gradient necessary for ATP synthesis.
9	Compare and contrast the ATP yield from glycolysis, the Krebs cycle, and oxidative phosphorylation.	Glycolysis yields a small net of 2 ATP. The Krebs cycle produces 2 ATP (or GTP) per glucose. Oxidative phosphorylation is the major ATP producer, yielding approximately 30-34 ATP molecules per glucose molecule, due to the energy extracted and used from electron carriers.
10	What is the overall equation for aerobic cellular respiration?	The overall equation for aerobic cellular respiration is: C ₆ H ₁₂ O ₆ (glucose) + 6O ₂ (oxygen) → 6CO ₂ (carbon dioxide) + 6H ₂ O (water) + ATP (energy).
